INTERVAL EXPLOSION SEARCH ALGORITHM AND ITS APPLICATION TO HYPERSONIC AIRCRAFT MODELLING AND MOTION OPTIMIZATION PROBLEMS

A.V. Panteleev, Moscow Aviation Institute, Moscow, Russian Federation, avpanteleev@inbox.ru, V.N. Panovskiy, Moscow Aviation Institute, Moscow, Russian Federation, panovskiy.v@yandex.ru, T.I. Korotkova, Moscow Aviation Institute, Moscow, Russian Federation, tatyanamail11@yandex.ru

This work considers hypersonic aircraft open-loop control problem in a presence of terminal and phase constraints. By the discretization process this problem is transformed into a nonlinear programming problem which is solved numerically by the interval explosion search algorithm. This algorithm belongs to metaheuristic algorithms of interval global optimization. Desired control is constructed in a class of interval piecewise-constant and piecewise-linear functions. Also this work demonstrates the comparison of results obtained by the proposed method and by Galerkin projection technique. This comparison confirms the efficiency of the interval based control algorithm.

Keywords: interval analysis; interval explosion search; optimization; optimal control; hypersonic aircraft.

Introduction

Development of hypersonic aerial vehicle (HAV) control techniques is very urgent field of applied cybernetics [1]. One of possible opportunities consists in spaceplane creation. Spaceplane is a special type of spacecraft which can soar and hurtle as an ordinary plane. In consequence of principally different interaction between HAV and atmosphere all proposed methods should be analyzed accurately to find out advantages and disadvantages. To raise accuracy it is important to develop new numerical methods using metaheuristic and interval optimization algorithms [1–3], which can give an appropriate solution for the HAV optimal open-loop control problem.

Existing numerical methods of optimal control include various methods which use Pontryagin’s maximum principle and Bellman’s equation, direct methods (e.g. gradient methods, first-ordered methods), second-ordered methods which are based on a Taylor approximation of Krotov – Bellman function, different improvement methods and etc. [4,5]. There is a need in development of new approaches in order to improve the efficiency and accuracy. Such an approach consists in the use of interval analysis coupled with metaheuristic strategies [2,3].

Interval analysis [6–10] is used as the main component of interval explosion search (IES). Existing interval optimization methods can be divided into a few groups:

- methods of unconstrained optimization (Moore – Skelboe algorithm, Ichida – Fujii algorithm, Dussel algorithm, interval simulated annealing, graph subdivision method and etc. [11–13]),
- methods of constrained optimization (Hansen method, Moore method and etc. [7,9]).
IES belongs to the group of so called metaheuristic algorithms. Metaheuristic algorithms give admissible solutions in the most practically significant cases. Such algorithms do not guarantee obtaining the best solution, but the main advantage is that they have lower computational complexity. Thus they can be applied to complicated problems without additional constraints on problem statement (differentiability, convexity and etc.). Also these methods do not use necessary and sufficient optimality conditions [1]. Metaheuristic algorithms combine one or several heuristic procedures which base on the higher level strategy.

In the following work it will be shown how general open-loop control problem can be transformed into the form of interval constrained global optimization problem which will be solved numerically with the IES. Method efficiency is demonstrated on the solution of HAV optimal control problem.

1. Interval Analysis. Definitions and Notations

The main idea of interval analysis [6-10] is that real numbers are surrounded with intervals and real vectors – with interval vectors, or boxes. Hereafter, lowercase letters in square brackets \([a] = [a_l; a_u]\) will be used to denote intervals and bold lowercase letters in square brackets \([\mathbf{a}] = [a_1] \times \ldots \times [a_n]\) – for boxes.

Each interval has the following characteristics:

- lower bound: \(a = \text{sup} \{ \xi \in \mathbb{R} \cup \{-\infty, \infty\} \mid \forall \zeta \in [a] : \xi \leq \zeta \};
- upper bound: \(\overline{a} = \text{inf} \{ \xi \in \mathbb{R} \cup \{-\infty, \infty\} \mid \forall \zeta \in [a] : \zeta \leq \xi \};
- width of nonempty interval: \(\omega ([a]) = [\overline{a}] - [a];
- midpoint of nonempty and finite interval: \(\text{mid} ([a]) = \frac{[a] + [\overline{a}]}{2}\).

The same parameters are defined for boxes. Lower and upper bounds and midpoint become vectors, width is now calculated as maximum of component’s widths.

Interval hull of a set \(X \subset \mathbb{R}^n\) is the smallest box (box with minimum width) \([X]\), that contains \(X\). If the set is surrounded by square brackets it means that we consider the interval hull.

Let \(\circ\) be a binary operation, then \([x] \circ [y] = \{[\xi_1 \circ \xi_2] \mid \xi_1 \in [x], \xi_2 \in [y]\};\) let \(f\) be an unary operator, then \(f ([x]) = \{(f (\xi )) \mid \xi \in [x]\}.$

The set of intervals is designated by \(\mathbb{IR}\), set of boxes – by \(\mathbb{IR}^n\). Consider a function \(f\) from \(\mathbb{R}^n\) to \(\mathbb{R}\). The interval function \([f]\) from \(\mathbb{IR}^n\) to \(\mathbb{IR}\) is an inclusion function for \(f\) if \(\forall [x] \in \mathbb{IR}^n, f ([x]) \subset [f ([x])]\). Inclusion function allows to get a priori estimate of function’s range even if it is nonconvex or disconnected. If all variables are substituted with intervals and all operations are done by the rules of interval arithmetic such a value is called an estimation of a direct function image.

2. Interval \(\varepsilon\)-Minimization Problem

Consider a given box \([s]\) and a cost function \(f : \mathbb{R}^n \rightarrow \mathbb{R}\). Interval \(\varepsilon\)-minimization problem consists in determination of such a box \([\mathbf{p}]^* \subset [s]\) that

\[\omega ([\mathbf{p}]^*) \leq \varepsilon, \# [x] \subseteq [s], \omega ([x]) \geq \varepsilon, [f ([x])] < [f ([\mathbf{p}]^*)]\] (1)

where the value \(\varepsilon\) affects the width of the \([\mathbf{p}]^*\) box.
3. Strategy of Interval Explosion Search (IES)

During the initialization bombs are randomly placed on the search area. Each bomb is associated with the box which describes its location. Moreover, all bombs are sorted (by ascending) by the lower bound of its direct function image estimation. IES has two iterative phases (Fig. 1): global and refining search, which differ from each other by the explosion procedure realization. Each iterative phase consists of:

1) bomb power calculation (power vector affects splinter scatter radius),
2) explosion procedure (during this procedure each bomb produces two splinters (new interval vectors) which scatter into different directions),
3) bomb list renewal.

Algorithm terminates when the maximum number of iterations is exceeded. From the bomb list we choose the one with the minimum lower bound of its direct function image estimation.

4. IES Algorithm

Step 1. Set iteration number \( t^g = 0 \), maximum number of global and refining search \( t^g_{\text{max}} \) and \( t^c_{\text{max}} \), maximum number of bombs \( B_{\text{max}} \), power vector \( r_{\text{max}} \in \mathbb{R}^n \), search area \([s]\) and \( \varepsilon = 2^{-\frac{t_{\text{max}}+t_{\text{max}}^c}{n}} \cdot \omega([s]) \).

Step 2. Randomly distribute bombs (interval vectors) on the search area: \([b] = [\xi_1; \zeta_1] \times \ldots \times [\xi_n; \zeta_n]^i \), where \( \xi_j \) and \( \zeta_j \) are random numbers which are uniformly distributed over interval \([s_j]\) (if \( \xi_j > \zeta_j \), then the corresponding interval is substituted with the interval \([\zeta_j; \xi_j]\)). Sort bombs by ascending of the lower bound of the direct function image estimation.

Step 3. Bomb power calculation. For each bomb \([b]_i\) from the list calculate its power vector: \( p^i = \frac{i-1}{B_{\text{max}}-1} \cdot r_{\text{max}}, i = 1, \ldots, B_{\text{max}} \).

Step 4. Explosion (global search). During this step each bomb produces two splinters by the bisection procedure. Bisection is a division along the widest component \([s]\). Thus
we obtain two new bombs from the given one: \( [b]_i = \left( \begin{pmatrix} [b_1]_i \\ \vdots \\ [b_k]_i \\ \vdots \\ [b_n]_i \end{pmatrix} + \begin{pmatrix} \xi (-p_{i1}; p_{i1}^i) \\ \vdots \\ \xi (-p_{ik}; p_{ik}^i) \\ \vdots \\ \xi (-p_{in}; p_{in}^i) \end{pmatrix} \right) \cap [s] \)

and \( [b]_{B_{\text{max}}+i} = \left( \begin{pmatrix} [b_1]_i \\ \vdots \\ [b_k]_i \\ \vdots \\ [b_n]_i \end{pmatrix} + \begin{pmatrix} \xi (-p_{i1}; 0) \\ \vdots \\ \xi (-p_{ik}; 0) \\ \vdots \\ \xi (-p_{in}; 0) \end{pmatrix} \right) \cap [s] \), where \( \xi (a; b) \) is a random variable uniformly distributed on interval \([a; b]\), \( k = \text{Arg}_{j=1,\ldots,n} \max \omega ([b_j]_i) \).

Step 5. Bomb list renewal. On the previous step number of bombs has been doubled. Thus unnecessary ones should be removed; sort bombs in ascending order by the lower bound of the direct function image estimation. Remove last \( B_{\text{max}} \) bombs.

Step 6. Increase \( t^g \) by 1. If \( t^g < t^g_{\text{max}} \) then return to step 3, otherwise go to step 7.

Step 7. Set iteration number \( t^c = 0 \).

Step 8. Bomb power calculation. For each bomb \( [b]_i \) from the list calculate its power vector: \( p^i = \frac{t^c - 1}{B_{\text{max}} - 1} \cdot r_{\text{max}}, \ i = 1, \ldots, B_{\text{max}} \).

Step 9. Explosion (refining search). During this step each bomb produces two splinters by the bisection procedure. Bisection is a division along the widest component \([8]\). Thus we obtain two new bombs from the given one: \( [b]_i = \left( \begin{pmatrix} [b_1]_i \\ \vdots \\ [b_k]_i \\ \vdots \\ [b_n]_i \end{pmatrix} + \begin{pmatrix} 0 \\ \vdots \\ \xi (0; p_{ik}^i) \\ \vdots \\ 0 \end{pmatrix} \right) \cap [s] \)

and \( [b]_{B_{\text{max}}+i} = \left( \begin{pmatrix} [b_1]_i \\ \vdots \\ [b_k]_i \\ \vdots \\ [b_n]_i \end{pmatrix} + \begin{pmatrix} 0 \\ \vdots \\ \xi (-p_{ik}; 0) \\ \vdots \\ 0 \end{pmatrix} \right) \cap [s], \ k = \text{Arg}_{j=1,\ldots,n} \max \omega ([b_j]_i) \).

Step 10. Bomb list renewal. Sort bombs in ascending order by the lower bound of the direct function image estimation. Remove last \( B_{\text{max}} \) bombs.

Step 11. Increase \( t^c \) by 1. If \( t^c < t^c_{\text{max}} \) then return to step 8, otherwise go to step 12.

Step 12. Choose the box which is associated with the bomb with the smallest lower bound of the direct function image estimation as a problem solution \([p]^*\). Find \([f] ([p]^*)\) as a cost function interval.

5. Optimal Open-Loop Control of Continuous Deterministic Systems

Behaviour of control object is described by differential equation \([16]\):

\[ \dot{x}(t) = f(x(t), u(t)), \quad (2) \]
where \( t \in T = [t_0; t_1] \) is continuous time, \( T \) is the system operational time, \( x \in \mathbb{R}^n \) is the system state vector, \( u \in [u] \subset \mathbb{R}^q \) is a control vector, \([u]\) is a set of admissible control values (box), \( f (t, x, u) = (f_1 (t, x, u) , ..., f_n (t, x, u))^T \) is a continuous vector-function.

Initial state is given
\[
x (t_0) = x_0.
\]

Terminal state \( x (t_1) \) should satisfy the following interval terminal conditions:
\[
\Gamma_i (x (t_1)) \in [G_i] , i = 1, ..., l,
\]

where \( 0 \leq i \leq n \), \([G_i]\) are given intervals, functions \( \Gamma_i (x) \) are continuously differentiable, system of vectors \( \left\{ \frac{\partial \Gamma_i (x)}{\partial x_1}, ..., \frac{\partial \Gamma_i (x)}{\partial x_n} \right\} \), \( i = 1, ..., l \) is linearly independent \( \forall x \in \mathbb{R}^n \).

The only information which is used to form control is continuous time \( t \). Hence we consider open-loop control.

Set of admissible processes \( D (t_0, x_0) \) is defined as a set of pairs \( d = (x (\cdot) , u (\cdot)) \) which include trajectory \( x (\cdot) \) and admissible control \( u (\cdot) \), where \( \forall t \in T : u (t) \in [u] \) and state equation (2), initial condition (3) and terminal condition (4) are satisfied.

On the set of admissible processes we consider cost functional
\[
I (d) = \int_{t_0}^{t_1} f (t, x (t) , u (t)) dt + F (x (t_1)),
\]

where \( f^0 (t, x, u) \) and \( F (x) \) are given continuous functions.

In order to transform the given problem into a problem without terminal constraints (4) we can use penalty function:
\[
\mathcal{I} (d) = I (d) + \sum_{i=1}^{l} R_i^{(1)} \cdot H_i^{(1)},
\]

where \( H_i^{(1)} = h_{\infty}^2 ([\Gamma_i (x (t_1)); \Gamma_i (x (t_1))] ; [G_i]) \), \( h_{\infty} ([a] , [b]) = \inf \{ r | [a] \subset [b] + [-r; r] \} \) is a Hausdorff metric, \( R_i^{(1)} \) are penalty parameters.

If there are interval phase constraints \( \left\{ p_j (x (t), u (t), \dot{x} (t), \dot{u} (t)) \in [P_j] , \forall t \in T \right\}_{j=1}^{N_p} \), where \( p_j (\cdot) \) is the constraint function, \([P_j]\) are given intervals, \( N_p \) is the number of constraints, then we have another form of modified cost functional (5):
\[
\mathcal{I} (d) = I (d) + \sum_{i=1}^{l} R_i^{(1)} \cdot H_i^{(1)} + \sum_{j=1}^{N_p} R_j^{(2)} \cdot H_j^{(2)},
\]

where
\[
H_j^{(2)} = \int_{t_0}^{t_1} h_{\infty}^2 ([p_j (x (t), u (t), \dot{x} (t), \dot{u} (t)); p_j (x (t), u (t), \dot{x} (t), \dot{u} (t))] ; [P_j]) dt,
\]

\( R_j^{(2)} \) are penalty parameters.

The problem is to find such a pair \( d^* = (x^* (\cdot) , u^* (\cdot)) = \arg \min_{d \in D(t_0, x_0)} I (d) \).
6. Application of Interval Optimization Technique

We will consider interval control as a piecewise-constant or piecewise-linear interval function \([u](t)\) and interval trajectory as a piecewise-continuous interval function which satisfies (2) – (4).

The piecewise-constant control (Fig. 2 (a)) can be uniquely associated with an interval vector \([u_1(\tau_0)] \times \ldots \times [u_q(\tau_0)] \times \ldots \times [u_1(\tau_{N-1})] \times \ldots \times [u_q(\tau_{N-1})]\), where \(\tau_i = t_0 + \frac{t_i-t_0}{N} \cdot i\), \(N\) is number of discretization steps. Corresponding interval control can be found as follows: \([u](t) \in [u(\tau_i)], \tau_i \leq t < \tau_{i+1}, i = 0, \ldots, N-1\).

The piecewise-linear control (Fig. 2 (b)) can be uniquely associated with an interval vector \([u_1(\tau_0)] \times \ldots \times [u_q(\tau_0)] \times \ldots \times [u_1(\tau_N)] \times \ldots \times [u_q(\tau_N)]\). Corresponding interval control can be found as follows: \([u](t) \in \frac{\tau_{i+1} - t}{\tau_{i+1} - \tau_i} \cdot \frac{\tau_i - \tau_i}{\tau_{i+1} - \tau_i} \cdot [u(\tau_i)], \tau_i \leq t < \tau_{i+1}, i = 0, \ldots, N-1\).

\[\begin{array}{c}
\text{(a)} \\
\text{(b)}
\end{array}\]

**Fig. 2.** Piecewise-continuous interval control

It is suggested to find the interval vector, which satisfies condition (1), by the IES algorithm (optimization will be done on the search area \([s] = [u] \times \ldots \times [u]\) for the piecewise-constant interval control and \([s] = [u] \times \ldots \times [u]^{q(N)}\) for the piecewise-linear interval control).

The value of the cost function criterion (14) is calculated by the numerical methods using Euler, Euler – Cauchy or Runge – Kutta formulas [3] (all calculations on the right hand side of equations are done by the rules of interval arithmetic [6–10]).
7. HAV Optimal Open-Loop Control Problem

Consider the following system of differential equations [17] which describes HAV landing process:

\[
\begin{align*}
\dot{r}(t) &= V \cdot \sin \gamma, \\
\dot{\phi}(t) &= \frac{V \cdot \cos \gamma \cdot \sin \psi}{r}, \\
\dot{\gamma}(t) &= \frac{L \cdot \cos \sigma}{m \cdot r} + \left( \frac{V}{r} - \frac{g}{r} \right) + 2 \cdot \Omega \cdot \cos \phi \cdot \cos \psi + \\
&\quad \frac{2}{V} \cdot \cos \phi \cdot (\sin \gamma \cdot \cos \phi + \sin \gamma \cdot \sin \phi \cdot \sin \psi), \\
\dot{\psi}(t) &= \frac{L \cdot \sin \sigma}{m \cdot V \cdot \cos \gamma} - \frac{V}{r} \cdot \cos \gamma \cdot \cos \psi \cdot \tan \phi + 2 \cdot \Omega \cdot (\tan \gamma \cdot \cos \phi \cdot \sin \psi - \sin \phi) - \\
&\quad \frac{2}{V \cdot \cos \gamma} \cdot \sin \phi \cdot \cos \phi \cdot \cos \psi, \\
\end{align*}
\]

(8)

where \( r \) is the distance from the Earth center, \( \theta \) is the longitude, \( \phi \) is the latitude, \( V \) is the Earth-relative velocity, \( \gamma \) is the flight path slope, \( \psi \) is the velocity azimuth angle, \( \sigma \) is the roll angle, \( g = \frac{GM}{r^2} \) is the acceleration, \( GM \) is the Earth gravitational constant, \( \Omega \) is the Earth rotational velocity, \( m \) is the HAV mass, \( L = \frac{1}{2} \cdot \rho_0 \cdot e^{-\beta(r - r_0)} \cdot V^2 \cdot C_L \cdot S \) is the aerodynamic lift force, \( D = \frac{1}{2} \cdot \rho_0 \cdot e^{-\beta(r - r_0)} \cdot V^2 \cdot C_D \cdot S \) is the aerodynamic drag force, \( \rho_0 \) is the sea-level air density, \( \beta \) is the numerical coefficient, \( \rho_0 \) is the numerical constant, \( C_L, C_D \) are the aerodynamic force coefficients, \( S \) is the HAV surface area.

The aerodynamic force coefficients are defined by a polynomial function of Mach number \( M = \frac{V}{c} \) (\( V_s \) is sonic velocity) and attack angle \( \alpha \) basing on X-33 project information:

\[
\begin{align*}
C_L &= -0.0005225 \cdot \alpha^2 + 0.03506 \cdot \alpha - 0.04857 \cdot M + 0.1577, \\
C_D &= 0.001432 \cdot \alpha^2 + 0.00558 \cdot \alpha - 0.01048 \cdot M + 0.2204. \\
\end{align*}
\]

(9)

The numerical parameters which are used in the model: \( m = 35828 \text{ kg}, S \) is 149,3881 m², \( \rho_0 = 1,2256 \text{ kg/m}^3, r_0 = 1,2256 \text{ m}, \beta = 0,00013785 \text{ m}^{-1}, GM = 3,986 \cdot 10^{14} \text{ m}^3/s^2, \Omega = 0,000072722 \text{ rad/s}, R_e = 6378100 \text{ m}, V_e = 11180 \text{ m/s.} \)

The state vector consists of 6 components: \( x(t) = (r(t), \theta(t), \phi(t), V(t), \gamma(t), \psi(t))^T \). The HAV control is realized by washout and wash in angles: \( u(t) = (\alpha(t), \sigma(t))^T \).

The initial state of the system: \( r(t_0) = 6429100, \theta(t_0) = -85, \phi(t_0) = 30, V(t_0) = 2600, \gamma(t_0) = -1.3, \psi(t_0) = 0. \)

The HAV control vector:

\[
\begin{align*}
u(t) = (\alpha(t), \sigma(t)) \in [-10; 50] \times [-80; 80], \forall t \in T = [0; 530].
\end{align*}
\]

(10)

The terminal conditions:

\[
\begin{align*}
r(t_f) \in [6378578; 6378822], & \quad V(t_f) \in [91, 44; 91, 44], \\
\theta(t_f) \in [-80, 7126; -80, 7098], & \quad \gamma(t_f) \in [-6; -6], \\
\phi(t_f) \in [29, 998903; 30, 001097], & \quad \psi(t_f) \in [-60; -60].
\end{align*}
\]

(11)

The HAV trajectory phase constraints:

\[
\begin{align*}
q(t) \in [0; 14364, 1], & \quad h(t) = r(t) - R_e \in [0; 121920], \quad V(t) \in [0, 3; 5200], \\
Q(t) \in [0; 242000], & \quad \theta(t) \in [-90; 90], \quad \gamma(t) \in [-89; 89], \\
n^2(t) = \frac{n(t)}{g} \in [-2, 5; 2, 5], & \quad \phi(t) \in [-89; 89], \quad \psi(t) \in [-180; 180].
\end{align*}
\]

(12)
where \( q = \frac{1}{2} \rho_0 \cdot e^{-\beta (r - r_0)} \cdot V^2 \) is the dynamic pressure, \( Q = 4.477228 \cdot 10^{-9} \sqrt{\rho_0 \cdot e^{-\beta (r - r_0)}} \cdot V^3 \) is the rate of heat, \( n_z = \left| L \cdot \cos \alpha + D \cdot \sin \alpha \right| \) is normal acceleration.

The constraints on control vector rate:

\[
\dot{\alpha} (t) \in [-5; 5] \Leftrightarrow \frac{\alpha (t_{i+1}) - \alpha (t_i)}{\tau_{i+1} - \tau_i} \in [-5; 5],
\]

\[
\dot{\sigma} (t) \in [-5; 5] \Leftrightarrow \frac{\sigma (t_{i+1}) - \sigma (t_i)}{\tau_{i+1} - \tau_i} \in [-5; 5].
\]

The cost functional for the given problem:

\[
\bar{T} (d) = \sum_{i=1}^{6} R_i^{(1)} \cdot H_i^{(1)} + \sum_{j=1}^{11} R_j^{(2)} \cdot H_j^{(2)},
\]

where \( R_1^{(1)} = 1000, R_2^{(1)} = R_3^{(1)} = R_5^{(1)} = R_6^{(1)} = 1000000, R_4^{(1)} = 10000 \) and \( R_1^{(2)} = R_4^{(2)} = R_7^{(2)} = R_8^{(2)} = 10, R_2^{(2)} = R_3^{(2)} = R_5^{(2)} = R_6^{(2)} = R_9^{(2)} = 10000, R_{10}^{(2)} = R_{11}^{(2)} = 1 \).

It is required to find time histories of attack and roll angles, which minimize cost functional (14).

IES was implemented in a software complex, Visual Studio IDE and C# programming language. Parameters of the IES: \( t_{\text{max}}^g = t_{\text{max}}^r = 2500, B_{\text{max}} = 100, r_{\text{max}} = 0, 05 \) for each dimension.

Charts on Fig. 3 show the results from [17] which were obtained by B-splines and Galerkin projection technique.

\[ \text{Fig. 3. State vector components} \]

Charts on Fig. 4. show the results for the piecewise-constant interval control. Charts on Fig. 5 show the results for the piecewise-linear interval control.

Information about constraints satisfaction are represented in Tables 1, 2.

Thus, by comparison of the results we can conclude that IES algorithm can be efficiently applied to HAV optimal open-loop control problem. Obviously it is better to
use piecewise-linear control to satisfy constraints more accurately. All terminal and phase constraints were satisfied accurately enough.

Conclusion

In the present work IES algorithm based on metaheuristics and interval analysis is considered. The HAV optimal open-loop control problem is solved. Obtained results are compared with the results obtained by Galerkin projection technique.

Интервальный метод взрывов и его применение к задаче моделирования и оптимизации движения гиперзвукового летательного аппарата

А.В. Пантелейев, В.Н. Пановский, Т.И. Короткова

Рассматривается задача поиска оптимального программного управления гиперзвуковым летательным аппаратом при наличии термических и фазовых ограничений. С помощью процедуры дискретизации она сводится к задаче нелинейного программирования, которая решается с помощью интервального метода взрывов, относящегося к метаэвристическим алгоритмам интервальной глобальной оптимизации. Исходное управление ищется в классе интервальных кусочно-постоянных и кусочно-линейных функций. Приведено сравнение полученных результатов с известных и задача управления конечным положением гиперзвукового летательного аппарата, свидетельствующее об эффективности предложенного подхода.

Ключевые слова: интервальный анализ; интервальный метод взрывов; оптимизация; оптимальное управление; гиперзвуковой летательный аппарат.

Исследование выполнено при финансовой поддержке РФФИ в рамках научных проектов № 16-31-00115 мол_а, № 16-07-00419 А.
